Abstract: Igueben is located in the central of Edo State, Nigeria. It has neighbouring towns; Ogwa, Ugbegun, Ugiogba, Ebelle, and Ekpon. These towns have the same aquifer but significant variations in the water table. However this study was intended to unravel the salient ancient hydrological processes that occurred in the study area which resulted to this variation. Vertical electrical sounding (VES) data and borehole data of the area were integrated to generate geo-electrical resistivity section of the area, to identify the aquifer trends, body, and shape in order to re-construct the palaeo-sedimentation processes of the aquifers that underlie Iguebe and the neighbouring towns. The inversion model result for the seven VES conducted in the study area showed that the curve types are HQA, AHA, A, AHA, AHA, HAQ, and AQA, respectively. These type curve suggested that the aquifer type is arenite sandstone aquifer that has been transported from a long distance. The geo-electrical pattern and shape showed that Igueben and Ogwa (shallow marine) are the point of deposition from where other nearby towns (Ugbegun, Ugiogba, Ebelle, and Ekpon) sourced their aquifer by gravity settling from suspended sediments in water body into adjacent deep marine environment (Ugbegun, Ugiogba, Ebelle, and Ekpon). This geological processes were responsible for the variation in the water table in the study area.

Keywords: Igueben; aquifer; palaeo-sedimentation processes; geo-electrical resistivity; hydrogeological

1. Introduction

Palaeo-sedimentation processes of an aquifer are all the processes that had taken place in the past as at the time of transportation and deposition of an aquifer in a basin.1,3,11 These processes are controlled by sediment source availability, agents of weathering, transport media (glacier, wind, and water), proximity of source to basin, bio-chemical activities (Stow et al., 2001;9 VerStraetenet al., 2011),10 mechanical activities, and change in sea level (Brett et al., 2011;2 Ryan et al., 2015).8 Palaeo-environment where these processes occurred determines the yield of an aquifer. These processes determine the character of an aquifer (Woodrow, 1985;11,13 Gary, 2009).3 Hence the knowledge about the palaeo-sedimentation of an aquifer is a clue to the aquifer characteristics. However, aquifer formed by these processes can be altered by geological processes such as erosion and tectonic activities.

Igueben has been known to have groundwater occurrence at both shallow depths (120-140m) and deep depths (220m and above) while Ugiogba, Ugbegun, Ebelle, and Ekpon that are neighbouring towns have deep aquifers. However, borehole data in these towns have shown that the aquifer comprises the same derived properties such as fine grained sandstone facies. This present study is geared at unravelling the salient hydrological processes that occur in the study area by re-constructing the Palaeo-sedimentation processes of the aquifers that underlie Iguebe and the neighbouring towns using geo-electrical section and borehole data of the areas to characterize the aquifers according to the aquifer’s sandstone type (Aigbedion and Salufu, 2021),11 aquifer deposition environment, hydraulic head of the aquifers and make comparison.

2. Experimental section

2.1. Location and Local Geology

The study area is located in the part of Edo central. It comprises Igueben, Ugiogba, Ugbegun, Ogwa, Ebelle, and Ekpon (Fig. 1) in Iguebe Local Government Area of Edo State, Nigeria. The area is accessible by major road, Uromi-Agbor Road, and other minor roads (Fig. 1).

The area is underlain by clayey sandstone and lateritic sandstone facies that belong to Ogwashi-Asaba Formation. The lateritic sandstone facies covers Ugbegun, Ugiogba, Ogwa, Igueben, and Ebelle while Ekpon is covered by clayey sandstone facies (Fig. 2). The sandstones have general dip direction of south east direction with 5° dip (Fig. 2). The sandstones are reddish to brown and friable.
2.1. Methods

Seven Vertical Electrical Sounding (VES) were conducted in Iguebe and environs using Schlumberger array (Fig. 3) to determine the depth of water table and depth of aquifer occurrence in each town. Borehole data were obtained from four existing wells across the study area. The result of seven VES obtained in the area was integrated with the borehole data to generate geo-electrical resistivity section of the area. The motive of the geo-electrical section of the study area was used to characterize the aquifer and infer the palaeo-sedimentation processes that had taken place in the course of aquifer deposition in the area. Thus salient information useful to the modeling of the hydrogeological setting of the area was deduced.

2.3. Mathematical Theory

As the fluid flow into the basin or from one part of the basin to another part in the time past, the fluid carried sediments along and got deposited into the basin as fluid mass. The fluid masses either gained or lose velocity by moving into an area where the velocity had changed in time at any position. The deposited sediments can be aquifer, aquitard or aquiclude. The total fluid acceleration during sedimentation in a basin is given as

\[ \frac{Du}{Dt} = \frac{D}{Ds} + \left( \frac{Ds}{Ds} \right) \tag{1} \]

Expanding into 3D coordinate equation (2) becomes:

\[ \frac{Du}{Dt} = \frac{D}{Ds} + \left( \frac{D}{Dy} + \frac{D}{Dx} \right) \tag{2} \]

Thus, equation (2) can be transformed to:

\[ \frac{Du}{Dt} = \frac{D}{Dx} + \mu \nabla u \tag{3} \]

Aquifer that is deposited in a basin can be located by VES using the basic principle of ohm’s law:

\[ R = \frac{V}{I} \tag{4} \]

Resistivity in equation (4) is the measured resistivity by terameter. The true resistivity of the subsurface is gotten by multiplying equation (4) with geoelectric factor (K) to have apparent resistivity (\( \rho_a \)).

\[ \rho_a = K \frac{V}{I} \tag{5} \]

K is computed using the general equation (6)
Let the separations of current and potential electrodes in Fig. 3 be L and a, respectively. General equation is given as:

\[ \rho_a = 2\pi \frac{V}{I} \left[ \frac{1}{(L-a)^2} \right] \tag{6} \]

Then

\[ A = D = \frac{(L-2)}{2} \tag{7} \]

\[ C = B = \frac{(L-2)}{2} \tag{8} \]

Substituting in equation (6)

\[ \rho_a = 2\pi \frac{V}{I} \left[ \frac{1}{(L-a)^2} \right] \tag{9} \]

Hence, equation (9) becomes:

\[ \rho_a = \frac{\pi V}{4 I} \left( \frac{L^2-a^2}{a} \right) \tag{10} \]
Subsequently, Res1Dinvers was used to carry out the inversion model to produce a model response that matches the measured values by using the least-squares optimization method after Lines and Treitel (1984) [7] according to equation (11) as shown below:

\[ J^T J + \lambda I \Delta q = J^T g \]  \hspace{1cm} (11)

The damping factor effectually constrains the range of values that the components of parameter change vector \( \Delta q \) take. The damped least-squares method attempts to minimize a combination of the magnitude of the discrepancy vector and the parameter change vector.

### 3. Results and Discussions

The result of raw field resistivity data acquired in the study area is given in Table 1. The inversion model is given in Fig. 4 to Fig. 10. The inversion model for the seven VES conducted in the study area showed that the curve types for the seven VES are HQA, AHA, A, AHA, AHA, HAQ, and AQA, respectively. The pattern of the curve type showed that the aquifers are arenite sandstone that had undergone second cycle sediment recycled probably from a long distance. The resistivity results for the seven VES acquired in the study area showed that Ogwa and Iguebe have the shallowest water table 110m and 120, respectively. However, Iguebe result indicated that Iguebe has two distinct water table; shallow and deep; 120m and 220m, respectively. The shallow water table is restricted to the northern
part of Iguebe while the deep water table occurs in the southern part. Ugiogba, Ugbegun, Ebelle, and Ekpon, have deep water table; 240m, 250m, 230m, and 240m, respectively.

3.1. Re-Construction of Palaeo-sedimentation Processes of Iguebe and Environs

The integration of resistivity section and the borehole data in the study area obviously revealed the fact that the aquifer deposits depth was shallow at Iguebe north and Ogwa, thus became deepening towards the south and extreme north of the study area in Iguebe south, Ugbegun, Ugiogba, Ebelle, and Ekpon. They are located as shown in the geo-electrical resistivity section of the study area (Fig. 11). The bore data (Fig. 12) in the study area confirmed this fact. The pattern of the geo-electrical section showed that Ogwa and Iguebe north represented the point in the ancient sea where river flowed into the standing body of water (sea). The sediment continued to get deposited at the mouth of the standing sea and subsequently got distributed to deeper part (Ugiogba, Ugbegun, Iguebe south, Ebelle, and Ekpon) of the ancient sea by the flow of the river into the sea, in response to the gravity.

The grain size of very fine grained sandstone and siltstone sequence (Fig. 12) that majorly the character of the aquifers in the study area corroborated the fact that the sandstone were transported from very far distance into the basin (sea) later moved from the mouth of the sea (shallow part) to other deeper parts as suspended load within the water body (sea). The motive of the geo-electrical section and litho-log of boreholes section indicates Ogwa and Iguebe north to be the hydraulic head (HH) of the entire aquifers in the study area (Fig. 12). This is due to the manner the palaeo sedimentation processes occurred in the area. Thus groundwater moved from the Ogwa and Iguebe north radially to other aquifers around them. Hence the aquifer that underlies the study area was deposited in a transitional (tidal flat) between marine and fluvial where wave energy washed silt and clay away, leaving sandstone particles behind.

4. Conclusions

Palaeo-sedimentation processes of Iguebe and environs has been successfully carried out using integrated data of vertical electrical resistivity and borehole in the area to generate geo-electrical resistivity section of the aquifer that underlies the area in order to
re-construct the aquifer trends and body, to delineate the ancient geological processes that led to the deposition of the aquifer and the palaeo-environment of the aquifer. The study has shown that Iguebe north and Ogwa are the depo-center where wave energy from marine environment washed the transported sandstone from far source and distributed it to deeper parts (Iguebe south, Ugbegun, Ugiogba, Ebelle, and Ekpon) of the marine by suspension of particles that settled down due to gravity effect. This was responsible for the variations in the water table across the study area.
